

Comparative Study on Conventional Slab & Flat Slab System Using Overhanging Column For Seismic Zone-3 Using Staad Pro Software

Divya Sagar¹, Nitesh Kushwaha²

¹M. Tech. Scholar, ²Professor Department of Civil Engineering, Millennium Institute of Technology, Bhopal India

Abstract - A reinforced concrete flat slab, also called as beamless slab, is a slab supported directly by columns without beams. A part of the slab bound on each of the four sides by centre lines of columns is called a panel. The flat slab is often thickened near to supporting columns to provide adequate strength in shear and to reduce the quantity of negative reinforcement in the support regions. The main difference between flat slab & conventional slab-beam system is that the one is directly supported on the column while another system has a beam for support. This study on conventional slab & flat slab system using overhanging column for seismic zone-3 using staad pro software. For this analysis we used STAAD. Pro software and prepare model for same height, same plan and same loading condition. We are taking a G+8 -story building for analysis having 28.8 m height from ground level and 19 x 20 m is plan.

I. INTRODUCTION

- The economic growth and rapid urbanization in hilly region has accelerated the real estate development and resulted in increase in population density in the hilly region enormously. Therefore, there is popular and pressing demand for the construction of multi-storey The main objective of the analysis is to study the behaviour against different forces acting on components of a multistoried building.
- With rapid growth in population along with development of industrial and commercial activities rapid urbanization has taken place which has resulted into continues influx of rural people to metro cities. So obviously the horizontal space constraint is reaching an alarming situation for metros.
- To cope with the situation maximum utilization of space vertically calls for the construction of multistorey buildings in large numbers but the question of affordability of the target customers mainly the middle income group of our country necessitates efficient and cost effect design of such buildings.

II. OBJECTIVES

• Comparative study on conventional slab & flat slab system using overhanging column for seismic zone-3

using staad pro software.

III. METHODOLOGY

4.1 General :

study on conventional slab & flat slab system using overhanging column for seismic zone-3 using staad pro software are modeled and analyzed for the different combinations of static loading. The comparison is made between the conventional slab & flat slab system structure situated in seismic zone III. Different cases of building considered are as given below :

Case-1: analysis of Building without overhanging columns with conventional slab

Case-2: analysis of Building having Overhanging Columns with conventional Slab.

Case-3: analysis of Building without overhanging columns With Flat slab.

Case-4: analysis of Building having Overhanging Columns with Flat Slab

In this study the behavior of building frame with and without overhanging columnis studied under static load, Dynamic load and seismic loading condition. The Response Spectrum method is adopted for dynamic analysis in the STAAD. Pro. Four G+8 Storey two bay 3D building frame with and without overhanging columns are analyzed for static loading using the present FEM code and for dynamic loading using Response Spectrum method. For analysis of the commercial software *STAAD Pro*. For this study we design a G+8 Storey building tower with all columns supporting to the ground and another same building is design with overhanging columns. These columns are supported by a shear wall provided in place of brick masonry wall.

IV. RESULT ANALYSIS

In this example two concrete frames with and without overhanging column having same material property and dimension are analyzed under same loading condition.

After finishing comparative study of the building's towers Analysis of G+8 storied buildings with Conventional slab & flat slab system using with & without overhanging column system in zone III a comparison is made on the basis of following points given bellow. Then final result is obtained by reading these tables.

(1) MAXIMUM & MINIMUM SHARE FORCE

I)ITE

(2) MAXIMUM & MINIMUM AXIAL LOAD ON COLUMNS FOOTING

(3) MAXIMUM & MINIMUM BENDING MOMENT

(4) MAXIMUM & MINIMUM DISPLACEMENT OF BEAMS

Table 5.11 Axial load on columns of building having flat slab without overhanging columns.

Fig. 5.12– STAAD. Pro Model showing Nodal displacement in Building having conventional slab with overhanging columns

V. CONCLUSIONS

Based on Analysis of Flat slab building and Conventional R.C. framed buildings using overhanging column, the following conclusions are drawn:

• In two building the conventional slab is provided and those of one building all the columns are supported directly to the ground and in other second building some columns are supported in shear wall in first floor not to the ground. These columns are termed as overhanging columns.

- In other remaining two building the flat slab is provided and those of one building all the columns are supported directly to the ground and in other second building some columns are supported in shear wall in first floor not to the ground. These columns are termed as overhanging columns.
- The vertical load and moment are more in columns supporting the shear walls. Hence there are need to increase the sizes of these columns.
- Hence there are more chances of settlement of these columns carrying heavy load or need to greater strength in footing.
- The maximum +Vemoment in the building having conventional slab without overhanging columns is 4323.771N-m and for the building with overhanging columns is 23119.341N-m. and maximum -Ve moment in the building having conventional slab without overhanging columns is -9134.434N-m and for the building with overhanging columns is -22586.825N-m. The detail comparison is given in Table No.-5.1 & 5.2.
- The maximum +Ve moment in the building having flat slab without overhanging columns is 6039.581 N-m and for the building with overhanging columns is 12351.728N-m. and maximum -Ve moment in the building having flat slab without overhanging columns is -6083.226 N-m and for the building with overhanging columns is -10496.261N-m. The detail comparison is given in Table No.-5.3& 5.4.
- The maximum shear force in the building having conventional slab without overhanging columns is 1419.943KN and for the building with overhanging columns is 1859.406KN. The detail comparison is given in Table No.-5.5& 5.6.
- The maximum shear force in the building having flat slab without overhanging columns is 678.561 KN and for the building with overhanging columns is 876.671 KN. The detail comparison is given in Table No.-5.7 & 5.8.
- The maximum axial load in the column building having conventional slab without overhanging columns is 175.291KN and for the building with overhanging columns is 233.911KN. The detail comparison is given in Table No.-5.9 & 5.10.
